Question 1

Consider two scenarios for a consumer planning consumption with income process $y_t = y_0 \delta^t$, $\forall t \geq 0$ and $F_0 = 0$.

Scenario 1 for Consumer The consumer maximizes the following welfare

$$U \equiv \max_{\{c_t, F_{t+1}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t \log(c_t)$$

$$\tag{1}$$

s.t.
$$F_{t+1} = R(F_t + y_t - c_t), \quad \forall t \ge 0$$
 (2)

Scenario 2 for Consumer The consumer faces the same problem as Scenario 1, except with **no borrowing**: $F_{t+1} \geq 0$ for all $t \geq 0$, and the initial level of y_0 is potentially different (define it as y_0^{NB})

Define the PDV of utility (i.e., the welfare) of this as U^{NB} .

- (a) Let $\beta = 0.95, R = 1.04, \delta = 1.02, y_0 = 1$, and $y_0^{NB} = 1$. Calculate U and U_{NB} .
- (b) Let $y_0 = 1$. Now find a y_0^{NB} such that $U = U^{NB}$. The difference between y_0 and y_0^{NB} is the amount of sacrifice in terms a consumer with a borrowing constraint would pay to be free to borrow. A measure of the welfare loss of the no borrowing constraint.
- (c) Maintain $y_0 = 1$. Now, let $\beta = .99$, R = 1.04, and $\delta = 1.01$. What is c_0 and F_1 here under Scenario 1? Repeat part (b) to find y_0^{NB} such that $U = U^{NB}$ with these new parameters. What can you conclude about the welfare cost of no borrowing in this case?

Question 2

Let the consumer have power utility,

$$u(c) = \frac{c^{1-\gamma}}{1-\gamma}, \quad \gamma > 1$$

Given $F_0 = 0, B \ge 0, \beta R = 1$, and the deterministic income stream $y_t = \delta^t$, the consumer maximizes

$$\max_{\{c_t, F_{t+1}\}_{t=0}^{\infty}} \sum_{t=0}^{\infty} \beta^t u(c_t) \tag{4}$$

s.t.
$$F_{t+1} = R(F_t + y_t - c_t), \quad \forall t \ge 0$$
 (5)

$$F_{t+1} \ge -B \tag{6}$$

$$F_0 = 0 (7)$$

(a) Derive the <u>euler equation</u> as an inequality, and the condition for it holding with equality.

- (b) Let $\delta > 1$ and $B = \infty$. What is $\{c_t\}_{t=0}^{\infty}$?
- (c) Let $\delta > 1$ and B = 0. What is $\{c_t\}_{t=0}^{\infty}$?
- (d) Let $\delta < 1$ and B = 0. What is $\{c_t\}_{t=0}^{\infty}$?
- (e) Assume that the consumer optimally eats their entire income each period, i.e., $c_t = y_t = \delta^t$ which implies $c_{t+1} = \delta c_t$. Setup, using dynamic programming, an equation to find the value V(c) recursively.
- (f) Guess that $V(c) = k_0 + k_1 c^{1-\gamma}$ for some undetermined k_0 and k_1 . Solve for k_0 and k_1 and evaluate V(1) (i.e., the value of starting with $c_0 = 1$.

Question 3

Consider a markov chain with two states: U for unemployment and E for employment.

- With probability $\lambda \in (0,1)$, a person unemployed today becomes employed tomorrow.
- With probability $\alpha \in (0,1)$, a person employed today becomes unemployed tomorrow.
- (a) Let $N \ge 1$ be the number of periods until a currently <u>unemployed</u> person becomes employed. Calculate $\mathbb{E}[N]$.
- (b) Let $M \geq 1$ be the number of periods until a currently <u>employed</u> person becomes unemployed. Calculate $\mathbb{E}[M]$.
- (c) Please compute the fraction of time an infinitely lived person can expect to be unemployed and the fraction of time they can expect to be employed.

Question 4

An economy has 3 states for workers:

- *U*: unemployment.
- V: if they have found a potential employer and are being verified to see if they are a good fit.
- E: if a worker has been verified and is employed.

The probabilities that they jump between these states each period is: i.e. probability γ they are a good fit, and the verification takes 1 period.

- (a) Write a Markov transition matrix for this process, P.
- (b) Write an expression for the stationary distribution across states in the economy, $\pi \in \mathbb{R}^3$ (You can leave in terms of P).
- (c) If a worker is U today, write an expression for the probability they will be employed exactly j periods in the future (considering any possible transitions which end in employment at j periods).².

¹Note that this equation deliberately is avoiding any t subscripts! This makes it a truly recursive expression.

²Note: This is only looking at j periods into the future. i.e. this is **not** the probability that they become at employed at least once during the j periods, which is a much more difficult calculation.

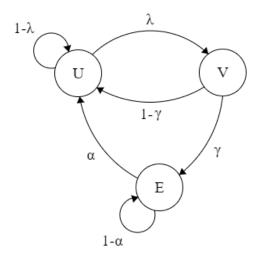

Figure 1: Markov Chain

(d) Assume that $\alpha=0, \lambda=0$. Is the stationary distribution unique? If not, describe the sorts of distributions that could exist and the intuition from the perspective of the Markov chain.
